MOTIVATION

Devices with limited sources are easy to get wired /attacked

We need cryptography implementation on these kinds of devices

ECC is one of the solution, but ECC needs big computation

Elliptic curve

$$y^2 = x^3 - x$$

$$y^2 = x^3 - \frac{1}{2}x + \frac{1}{2}$$

Elliptic curve over F_{23}

$$y^2 = x^3 + x + 1$$

Elliptic Curve Addition

Multiples in Elliptic Curves 1

- The interest in Elliptic Curve Addition is the process of adding a point to itself.
 - That is given a point P find the point $P+P$ or $2P$.
 - This is done by drawing a line tangent to P and reflecting the point at which it intercepts the curve
 - P can be added to itself k times resulting in a point $W = kP$.

Multiples in Elliptic Curves 1

Multiples in Elliptic Curves 2

- Finding the value of $3P$:

Elliptic Curve Encryption

- INPUT: Prime p , elliptic curve E , point P of order n , private key $d \in [1, n-1]$, plaintext m
- OUTPUT: Cipher text (C_1, C_2)
 1. Compute $Q = dP$
 2. Represent the message m as the point M in $E(\mathbb{F}_p)$
 3. Select $k \in [1, n-1]$
 4. Compute $C_1 = kP$
 5. Compute $C_2 = M + kQ$
 6. Return (C_1, C_2)

Elliptic Curve Decryption

- INPUT : prime p , elliptic curve E , point P of order n , private key d , ciphertext (C_1, C_2)
 - OUTPUT: Plaintext m
1. Compute $M = C_2 - dC_1$ and extract m from M
 2. Return (m) .

$$(M = C_2 - dC_1 = M + kQ - dkP = M + kdP - dkP)$$

Elliptic Curve Security

- The security of the Elliptic Curve algorithm is based on the fact that it is very difficult (as difficult as factoring) to solve the Elliptic Curve Discrete Logarithm Problem:

Given two points P and Q where $Q = kP$, find the value of k

POLLARD RHO

Let $G = E(\mathbb{F})$, with $|P| = M$, and P and Q such that $Q = [k]P$ in G . We aim to find k .

The Algorithm

1. By using a hash function, we divide G into 3 sets, S_1, S_2, S_3 with almost equal number of elements, but $O \notin S_2$.
2. Define an iteration function f :

$$R_{i+1} = f(R_i) = \begin{cases} P + R_i, & R_i \in S_1 \\ 2R_i, & R_i \in S_2 \\ Q + R_i, & R_i \in S_3 \end{cases} \quad (1)$$

Since $R_{i+1} = 2R_i$ if $R_i \in S_2$, then if O is in S_2 , in some time $R_i = O$ and the values of the iteration functions will all be O . That is why we make the assumption of $O \notin S_2$.

3. Let $R_i = s_iP + t_iQ$, then

$$s_{i+1} = \begin{cases} s_i + 1 & , R_i \in S_1 \\ 2s_i \bmod m & , R_i \in S_2 \\ s_i & , R_i \in S_3 \end{cases} \quad (2)$$

and

$$t_{i+1} = \begin{cases} t_i & , R_i \in S_1 \\ 2t_i \bmod m & , R_i \in S_2 \\ t_i + 1 & , R_i \in S_3 \end{cases} \quad (3)$$

4. Beginning with $R_0 = P, s_0 = 1, t_0 = 0$ we generate R_i until we find $R_j = R_l$ with $j \neq l$.

When we reach that equality, we will get

$$R_j = s_jP + t_jQ \text{ and } R_l = s_lP + t_lQ \quad (4)$$

And hence k is

$$k = \frac{s_l - s_j}{t_j - t_l} \bmod m \quad (5)$$

This algorithm can solve the ECDLP in $\mathcal{O}\sqrt{m}$ operation[10].(By the birthday paradox, the expected number of iterations for ordinary Pollard Rho is $\sqrt{\frac{\pi m}{2}}$)[1].

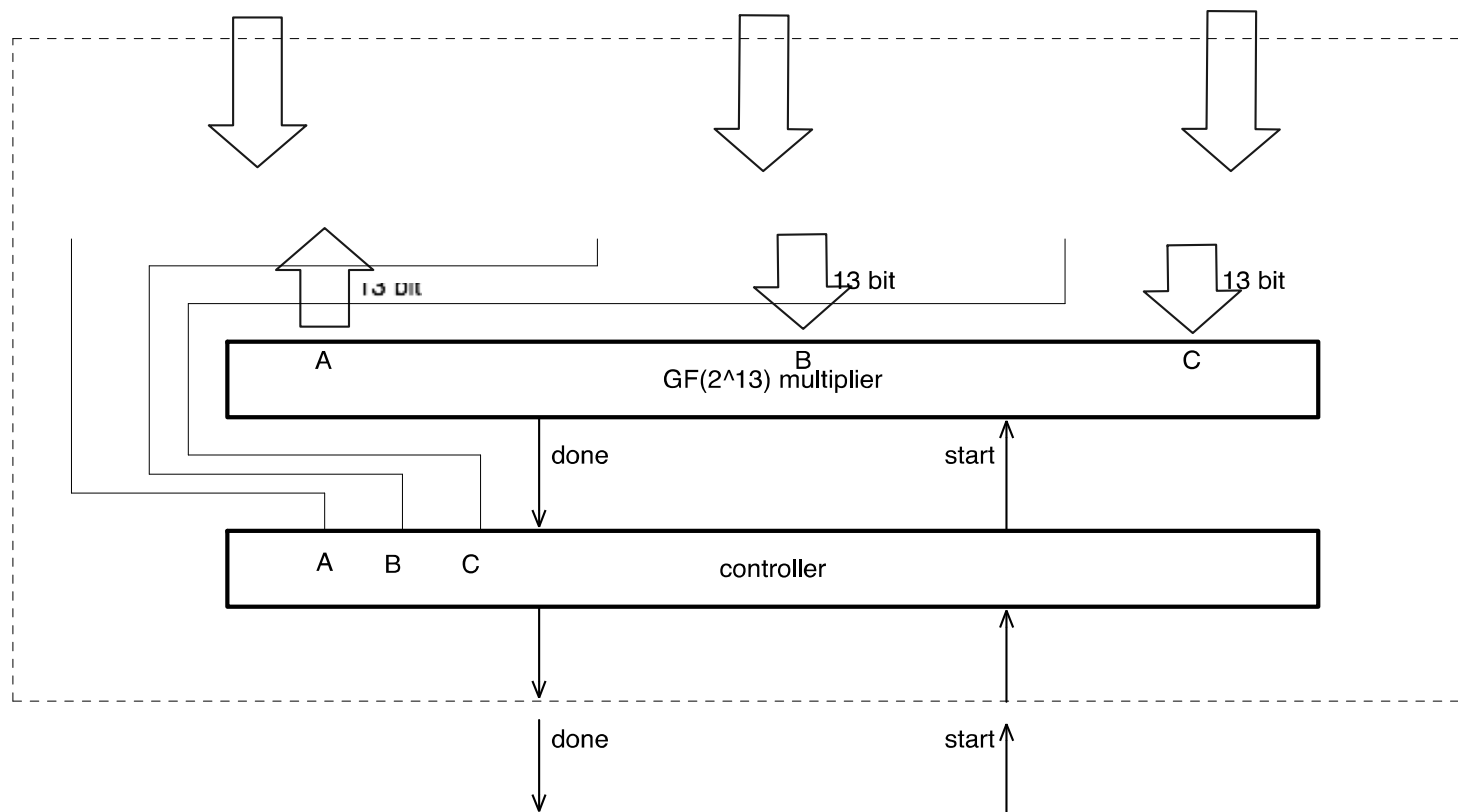

Finite Field

- Operations over the real numbers are slow and inaccurate due to round-off error
- Need to be faster and accurate
- Accurate and efficient :
 - Prime field $GF(p)$
 - Binary field $GF(2^m)$
 - Composite Field $GF((2^m)^n)$

MULTIPLIER

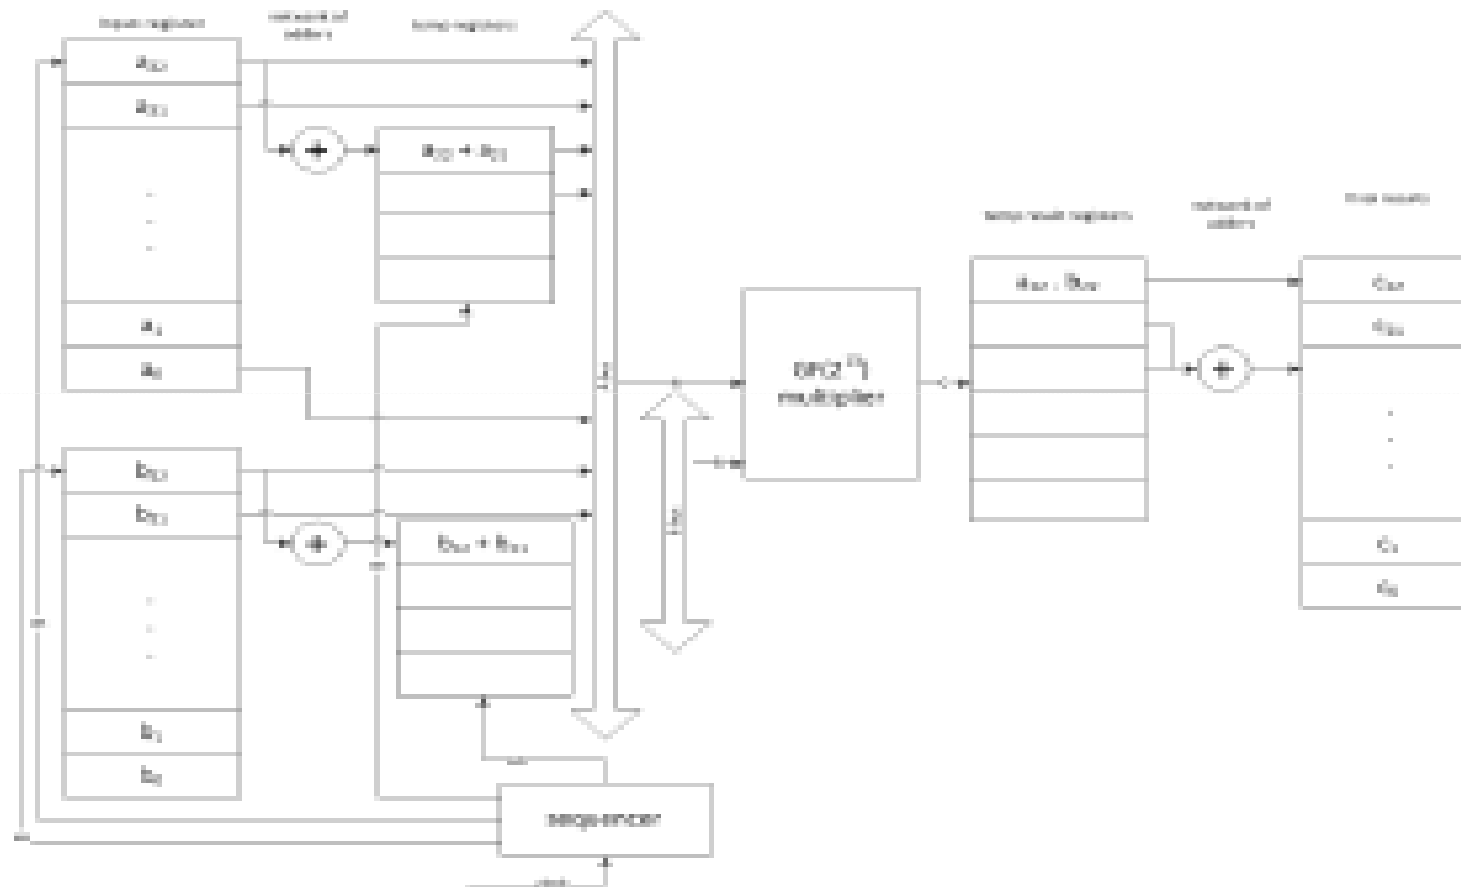

- MULTIPLIER :
 - Create/improve algorithms
 - Design implementation
- LUT is used for multiplication in ground field $GF(2^{13})$ and Karatsuba Offman Algorithm for the extension field multiplication $GF(2^{13})^{23}$

Multiplier for GF(2¹³)

[Paryasto2012]

Perbandingan Kompleksitas Pengali

[Paryasto2012]

Result 1 [Muchtadi2012]

- Speed up the Pollard Rho algorithm for elliptic curves over composite fields, by using the multiplier that combines the LUT and KOA proposed in [Paryasto2012]

Elliptic Curves over $GF(2^n)$

Elliptic curve over $GF(2^n)$ is defined with Weierstrass equation, which after transformed by admissible change of variables, can be written as

$$E(GF(2^n)) = \{(x, y) \in GF(2^n)^2 : y^2 + xy = x^3 + ax^2 + b\} \cup \{O\},$$

- where O is the projective closure of the equation .

Modified Pollard Rho

To speed up Pollard Rho, the iterating function f is defined on the equivalence class rather than just one point in $\langle P \rangle$.

The expected number of iterations for the modified Pollard Rho algorithm is

$$\sqrt{\frac{\pi m}{2t}}.$$

Negation Map

If $P = (x, y)$, we have $-P = (x, -y)$. The negation map $\psi(P) = -P$ has order 2, thus the number of iterations is expected to be

$$\frac{\sqrt{2n}}{2}$$

This map is applicable to all elliptic curve.

Frobenius Map

The Frobenius map can be used only for Koblitz curves. A Koblitz curve E_a (where $a \in \{0,1\}$) is an elliptic curve defined over $GF(2^n)$:

$$E_a : y^2 + xy = x^3 + ax^2 + 1.$$

The Frobenius map $\tau: E_n(GF(2^n)) \rightarrow E_n(GF(2^n))$ is defined by $\tau(O) = O$ and $\tau(x, y) = (x^2, y^2)$.

Pollard Rho algorithm using equivalence classes under the Frobenius map has an expected number of iterations

$$\sqrt{\frac{2n}{3}}$$

as the order of the map is n .

Furthermore, for Koblitz curves, the Pollard Rho's algorithm can exploit both the Frobenius and negation map to achieve an expected running time of

$$\frac{1}{2} \sqrt{\frac{2n}{3}}$$

Experimental Results1 [Muchtadi-Ardiansyah-Carita2013a]

Let $K = \mathbb{GF}(2^7)$.

$E =$ Elliptic Curve defined by $y^2 + x*y = x^3 + x^2 + 1$

Cardinality of $E = 142$

Let $P = R_0 = (3, 85)$ on E . The order of P is 71.

We choose $Q = 50P$

By using SAGE we compute R_i , as presented below:

i	R_i	$R_i = s_i P + t_i Q$	$-R_i$
0	(3, 85)	$1P + 0Q$	(3, 86)
1	(19, 29)	$1P + 1Q$	(19, 15)
2	(99, 5)	$2P + 1Q$	(99, 102)
3	(65, 119)	$3P + 1Q$	(65, 54)
4	(5, 119)	$3P + 2Q$	(5, 114)
5	(49, 23)	$3P + 3Q$	(49, 38)
6	(75, 126)	$4P + 3Q$	(75, 53)
7	(55, 56)	$4P + 4Q$	(55, 15)
8	(65, 119)	$8P + 8Q$	(65, 54)

We need 8 iterations to get $R_3 = R_8$. We get

$$3P + 1Q = 8P + 8Q$$

$$-5P = 7Q$$

$$66P = 7kP$$

$$k = (66/7) \bmod 71 = 50$$

Computation of Equivalence classes

The following is the computation of equivalence class of $R_1, R_2, R_3,$ and R_4 .

i		$\psi^i(R_1)$
1	$(R_1)^2$	(3,86)
2	$(R_1)^4$	(5,114)
3	$(R_1)^8$	(17,122)
4	$(R_1)^{16}$	(7,58)
5	$(R_1)^{32}$	(21,90)
6	$(R_1)^{64}$	(23,96)

i		$\psi^i(R_2)$
1	$(R_2)^2$	(125,17)
2	$(R_2)^4$	(47,7)
3	$(R_2)^8$	(77,21)
4	$(R_2)^{16}$	(49,23)
5	$(R_2)^{32}$	(31,19)
6	$(R_2)^{64}$	(83,3)

Equivalence class (contd)

i		$\psi^i(R_3)$
1	$(R_3)^2$	(97,107)
2	$(R_3)^4$	(121,61)
3	$(R_3)^8$	(63,79)
4	$(R_3)^{16}$	(75,53)
5	$(R_3)^{32}$	(37,15)
6	$(R_3)^{64}$	(9,85)

i		$\psi^i(R_4)$
1	$(R_4)^2$	(17,107)
2	$(R_4)^4$	(7,61)
3	$(R_4)^8$	(21,79)
4	$(R_4)^{16}$	(23,53)
5	$(R_4)^{32}$	(19,15)
6	$(R_4)^{64}$	(3,85)

Result with Frobenius

We can see that $\psi^6(R_0) = R_1 = P$.

Therefore $\psi^6(3P + 2Q) = P$. Since $\lambda = 103$,

$$3\psi^6(P) + 2\psi^6(Q) = P$$

$$3\lambda^6P + 2\lambda^6kP = P$$

Since $\lambda = 103$, we get $3(103)^6 + 2(103)^6k = 1$,
therefore $k = ((1 - 3(103)^6) / 2(103)^6) \bmod 71 = 50$.

Therefore, in this case, by using Frobenius map we just need 4 iterations to find two collision points. Note that we also need 6 times 4 squarings.

Result with Frobenius-Negation

Notice that $-P=(3,86)$, hence $\psi(R_1) = (R_1)^2 = -P$.

$$\psi(P + Q) = -P$$

$$103P + 103kP = -P$$

$$k = ((-1-103)/103) \bmod 71 = 50.$$

Therefore by Frobenius-Negation map we just need **one** iteration to get collision points.

Speeding the Squaring using Normal Basis

- A polynomial basis in $GF(2^n)$ is a basis of the form $\{1, \alpha, \alpha^2, \dots, \alpha^{n-1}\}$
- A normal basis in $GF(2^n)$ is a basis of the form $\{\alpha, \alpha^2, \dots, \alpha^{2^{n-1}}\}$
- In normal basis squaring is just a cyclic shift of the coordinates.

For example

- $w = 10110101$
- $w^2 = 11011010$
- $w^4 = 01101101$

Let A be the 13×13 matrix whose entries are binary numbers in the above table. If

$x = \begin{pmatrix} B[0] \\ B[1] \\ \vdots \\ B[12] \end{pmatrix}$ is a representation of an element of $GF(2^{13})$ in NB, then $x' = A^T x$

is its representation in PB. Note that A^T is invertible since elements of NB are linearly

independent. Therefore, let $x' = \begin{pmatrix} B[0]' \\ B[1]' \\ \vdots \\ B[12]' \end{pmatrix}$ be the representation of an element of $GF(2^{13})$

in PB, and let $(A^T)^{-1}$ be the inverse of A^T , we have $x = (A^T)^{-1} x'$, none other than its representation in PB. Thus, $(A^T)^{-1}$ is the transition matrix from PB to NB.

Experimental Result 2 [Muchtadi-Ardiansyah-Carita2013b]

Let $K = GF(2^{13})$,

$E =$ Koblitz Curve defined by $y^2 + xy = x^3 + x^2 + 1$

Cardinality of $E = 8374$. Let $P = X(0) = (9, 2951)$ on E . The order of P is 4187.

We choose $Q = 100P$

98	2594	5020	187	1665
99	53	3126	374	3330
100	6828	6345	748	2473

We need 100 iterations to get $X(29) = X(100)$. We get

$$276P + 133Q = 748P + 2473Q$$

$$-2340Q = 472P$$

$$1847kP = 472P$$

$$k = \left(\frac{472}{1847}\right) \bmod 4187$$

$$k = 100$$

We can see $X(65) = (5263, 4023)$ and its negation is $-X(65) = (5263, 6968)$. We get

$$-(3832P + 3216Q) = 1359P + 626Q$$

$$-3842Q = 13565P$$

$$345kP = 1004P$$

$$k = \left(\frac{1004}{345}\right) \bmod 4187$$

$$k = 100.$$

The use of Frobenius, Negation and Normal Basis

The following is the computation of equivalence class under Frobenius map of $X(1), X(2), \dots, X(20)$. We change it first into normal basis representation then we perform the squaring as cyclic shift.

In the following table we write down the elements of $GF(2^{13})$ as decimal. For example, in polynomial basis $\beta^7 + \beta^6 + \beta^4 + \beta^3 = 0000011011000 = 216$ and by Table 3, $\beta^7 + \beta^6 + \beta^4 + \beta^3 = \beta^{2^4} = 0000000010000$ in normal basis.

Table.5. Computation of equivalence class of X(1)

i	psi ⁱ	(X1) ⁱ [0]	(X1) ⁱ [1]

11	[X(20)] ²⁰⁴⁸	4084	3788
12	[X(20)] ⁴⁰⁹⁶	3333	2205

We can see that $\psi(X(16)) = \psi^2(X(20))$.

Therefore $\psi(32P + 14Q) = \psi^2(67P + 30Q)$. It easy to see that

$$32\psi(P) + 14\psi(kP) = 67\psi^2(P) + 30\psi^2(kP)$$

$$32\lambda(P) + 14\lambda(kP) = 67\lambda^2(P) + 30\lambda^2(kP)$$

Now we try to find λ . By [1, Note 3.72] we know that

$$\lambda^2 - \lambda + 2 \equiv 0 \pmod{4187}$$

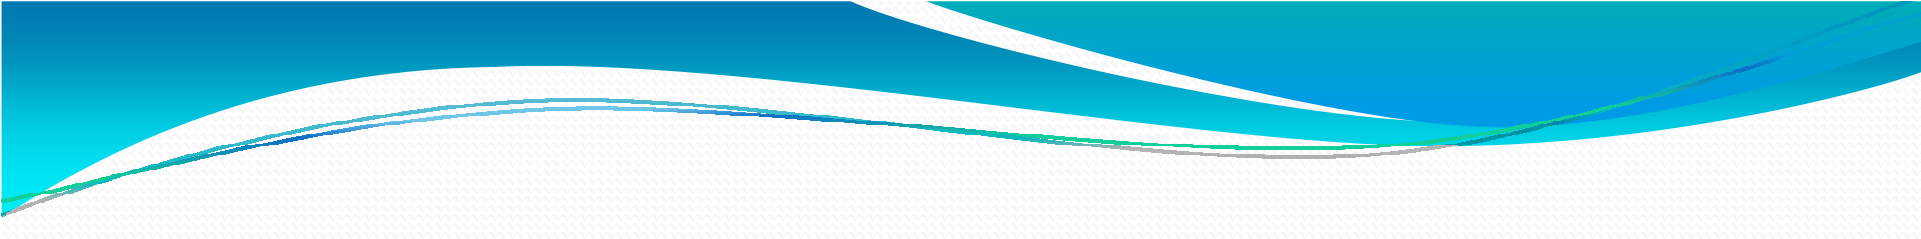

$$\lambda^2 - \lambda - (4185 + (4187 \cdot x)) = 0, x \in \mathbb{Z}$$

$$\text{Choose } x = 2, \lambda^2 - \lambda - 8372 = 0.$$

We can see that $\lambda = 92$ and $\lambda = -91 \equiv 4096 \pmod{4187}$ fulfill above equation. Therefore we may choose $\lambda = 4096$.

Since $\lambda = 4096$, we get $32(4096) + 14(4096)k = 67(4096)^2 + 30(4096)^2k$, hence $k = \frac{868}{1516} \pmod{4187} = 100$.

Therefore, in this case, by using Frobenius map we just need 20 iterations to find two collision points. Note that we also need 12 times squaring per iteration, which is easily done by cyclic shift.

Notice that $-\psi^{12}(X(8)) = \psi(X(11)) = (5672, 3138)$.

It means

$$-\psi^{12}(15P + 4Q) = \psi(30P + 11Q)$$

$$-15\lambda^{12}P - 4\lambda^{12}kP = 30\lambda P + 11\lambda kP$$

$$(11\lambda + 4\lambda^{12})kP = -(15\lambda^{12} + 30\lambda)P$$

$$(11(4096) + 4(4096)^{12})kP = -(15(4096)^{12} + 30(4096))P$$

$$k = \frac{2040}{4146} \pmod{4187}$$

$$k = 100$$

Therefore by Frobenius-Negation map we just need 11 iterations to get two collision points.

Comparison

The following is the comparison between the experimental results and the expected number of iterations explained in previous section:

Table 25. Comparison of number of iterations

Method	By Experiment	By Formule
	number of iterations	number of iterations
Ordinary	100	81.09~81
Negation	65	57.34~57
Frobenius	20	22.49~22
Frob-Neg	11	15.9~16

Implementation- for longer bit [Paryasto-Rahardjo2013]

Figure 1. Squaring process

```
void squarePB(int A[], int p[]){
    int i, j, k, x, y;
    int B[m], result[m];
    int p_long[m]; //to hold poly_irred in a longer
                    array, making computation easier
    int iteration;
    int flag = 1;

    for (i = 0; i < m; i++)
        p_long[i] = 0;

    for (i = 0; i <= n; i++)
        p_long[i] = p[i];
```

```

13
14 //initializing B[]
15 for (i = 0; i < m; i++){
16     B[i] = 0;
17     result[i] = 0;
18 }
19
20 j = n-1;
21 for (i = m-1; i >= n-1; i--){
22     B[i] = A[j];
23     j--;
24 }
25
26 if (A[n-1] == 1){
27     for (i = 0; i < m; i++)
28         result[i] = B[i];
29
30     for (k = n-2; k >= 0; k--){ //if bit 1, shift-left
        and xor           if (A[k] == 1){
31         //shifting B to the left one bit
32         for (i = 0; i < m-1; i++)
33             B[i] = B[i+1];
34             //and make sure to give trailing 0s
                B[m-1] = 0;
35
        //xor
36         for (i = 0; i < m; i++)
37             result[i] = result[i] ^ B[i];
38     }
39     else{ //if the bit is 0, just shift no xor
        //shifting B to the left one bit
40     for (i = 0; i < m-1; i++)
41         B[i] = B[i+1];
42
43     //and make sure to give trailing 0s
44     B[m-1] = 0;
45     }
46 }

```

$$P(x) = x^7 + x + 1 = 10000011$$

result 2 (final)	0000000100011	
	↓	
	$x^5 + x + x$	

Figure 2. Reduction process

```

1  //now is the part of reduction
2  iteration = 0;
3  k = 0;
4  while (flag == 1){
5      if (k >= m/2)
6          flag = 0;
7
8      if (result[k] == 1){ // do xor
9          iteration++;
10
11         j = 0;
12         for (i = 0; i < m; i++){
13             result[i] ^= p_long[j];
14             j++;
15         }
16
17         k = 0;
18     }
19     else{ //do shift to the right, no need xor-ing
20         iteration++;
21
22         //shifting result to the right one bit
23         for (i = m-1; i >=0; i--)
24             p_long[i] = p_long[i-1];
25
26         //make sure to give trailing 0s
27         p_long[0] = 0;
28
29         k++;
30     }
}

```

Conclusion

- By using Negation and Frobenius map simultaneously we can find two collision points faster than ordinary Pollard Rho.
- Random Walk is not always speeding up the Algorithm, should be combined with Frobenius-Negation.
- Unfortunately Frobenius only works for Koblitz curves
- Koblitz curves could be considered “weak”.
- To speed up the squaring for Frobenius, we suggest the use of normal basis.
